### Background

In neurons, the axon initial segment (AIS) is a specialised structure which marks the boundary between the somatodendritic and axonal compartments, and which is the site of action potential initiation.

The AIS is subdivided into distinct proximal and distal domains. This subdivision varies according to neuronal type, but a common feature is the aggregation of Na<sub>v</sub>1.6, K<sub>v</sub>1.1 and K<sub>v</sub>1.2 channels in the distal portion of the structure. It is this precise sub-region of the AIS where action potentials are believed to initiate.

In dissociated hippocampal cultures, we recently found that a prolonged period of depolarisation can produce relocation of the entire AIS. Components including the scaffolding protein ankyrin-G moved distally along the axon up to 17µm away from the soma.

So, given that the AIS is a subdivided structure, and that it relocates in response to changes in electrical activity...

Background images showing AIS structure and function. Includes a diagram of an action potential and a graph showing the distance along the axon for Na<sub>v</sub>1.6, K<sub>v</sub>1.1, and K<sub>v</sub>1.2 channels.

## What happens to AIS subdivision after activity-dependent relocation?

### ① Structural subdivision

Immunohistochemical labelling for voltage-gated ion channel subunits Na<sub>v</sub>1.6, K<sub>v</sub>1.1, or K<sub>v</sub>1.2 in conjunction with label for ankyrin-G (ankG) revealed clear structural subdivision of the AIS. In control dissociated hippocampal neurons at 14 days in vitro (DIV), Na<sub>v</sub>1.6, K<sub>v</sub>1.1 and K<sub>v</sub>1.2 label all occupied the distal-most portion of the ankG-defined AIS. This structural subdivision was maintained following activity-dependent AIS relocation: 48h treatment with 15mM K<sup>+</sup> caused a distal shift in overall AIS position, but no change in the distal localisation of Na<sub>v</sub>1.6, K<sub>v</sub>1.1 and K<sub>v</sub>1.2 channel subunits.

Structural subdivision graphs and images showing the distance along the axon for Na<sub>v</sub>1.6, K<sub>v</sub>1.1, and K<sub>v</sub>1.2 channels in control and 15mM K<sup>+</sup> conditions.

### Na<sub>v</sub>1.6

Na<sub>v</sub>1.6 AIS images and graphs showing the distance along the axon for Na<sub>v</sub>1.6 and AnkG in control and 15mM K<sup>+</sup> conditions.

### K<sub>v</sub>1.1

K<sub>v</sub>1.1 AIS images and graphs showing the distance along the axon for K<sub>v</sub>1.1 and AnkG in control and 15mM K<sup>+</sup> conditions.

### K<sub>v</sub>1.2

K<sub>v</sub>1.2 AIS images and graphs showing the distance along the axon for K<sub>v</sub>1.2 and AnkG in control and 15mM K<sup>+</sup> conditions.

### Summary

Summary diagram showing the AIS relocation process: Soma -> AIS -> Axon. Increased neuronal activity leads to a distal shift of the AIS.

### Are these structural effects mirrored by functional subdivision of the AIS?

Are these structural effects mirrored by functional subdivision of the AIS?

### ② Integrating AIS structure and function

The precise position of the AIS can be revealed in live neurons using an antibody raised against an extracellular domain of neurofascin-186 (eNF-186). These cells can then be targeted for whole-cell patch clamp recordings, without any effect of the live AIS label on fundamental action potential properties.

Integrating AIS structure and function graphs and images showing the relationship between AIS position and action potential properties.

### Functional subdivision I: Na<sup>+</sup> imaging

Loading live-AIS-labelled neurons with the sodium indicator dye CoroNa Green enables precise localisation of the axonal Na<sup>+</sup> transients associated with action potential firing. These can then be directly compared with the structurally-defined position of the AIS.

Functional subdivision I: Na<sup>+</sup> imaging graphs and images showing the relationship between AIS position and Na<sup>+</sup> transients.

### Functional subdivision II: extracellular recording

Live AIS structural label can also be combined with an electrophysiological estimate of the site of action potential initiation, based on the relative timing of somatic whole-cell action potentials and axonal extracellular spikes.

Functional subdivision II: extracellular recording graphs and images showing the relationship between AIS position and extracellular recordings.
